Abstract – New derivatives of pyrrolo[2,1-c][1,4]benzodiazepines were synthesized starting from a thiolactam and 2-bromoacetyl chlorides. Spectroscopic investigations and an X-Ray analysis are presented.

INTRODUCTION

Naturally occurring as well as synthetically prepared pyrrolo[2,1-c][1,4]benzodiazepines are biologically and pharmacologically highly interesting compounds as some of them recognize and bind to DNA and display cancerostatic and anti-infective properties.¹ The (S)-configuration of the α -C-atom of the pyrrolidine ring causes an isohelicity of this ring system with the minor groove of DNA,² so that tautomerism involving this position plays a crucial role for the biological activities of this class of compounds. We were interested in new derivatives of pyrrolobenzodiazepines and report here the syntheses and properties of thiazolidinone-annulated pyrrolobenzodiazepines which - to the best of our knowledge - are the first representatives of a new ring system. We focussed our attention on the potential tautomerism of the thiazole moiety, which is known to be complex³ and strongly influenced by the nature and location of the substituents, solvents and architecture of the molecule.⁴ Thus, three forms, thiazolidin-4-one, thiazol-4-ols as well as mesoionic partial structures had to be taken into consideration. The latter mentioned aromatic thioisomünchnone⁵ caused an intact (S)-configured pyrrolidine moiety of this biologically highly important ring system. The aromaticity indices, I_A indicate that the mesoionic forms have comparable aromaticities to the parent hydroxy thiazoles.⁶

RESULTS AND DISCUSSION

2-Bromoacetyl chloride and its 2-ethyl- and 2-phenyl-substituted derivatives converted the monothiolactam (**1**)⁷ at room temperature in THF into the 5,6-dihydro-4*H*-3-thia-6a,11*b*-diazabenz[*g*]cyclopenta[*e*]-azulene-1,7-diones (**2**) – (**4**). This reaction typically proceeds *via* intermediary iminium salts which can sometimes be trapped and used for heterocyclic synthesis.⁵ The treatment of the thiolactam (**1**) with 2-(4-nitrophenyl)-2-bromoacetyl chloride, however, resulted in the formation of a complex mixture of compounds from which no nitro derivative (**5**) could be isolated (Scheme 1). The formations of the thiazolidinones (**2A**) – (**4A**) in CDCl₃ and DMSO-*d*₆, respectively, were unambiguously proved by the existence of only three CH₂-groups (4-*H*, 5-*H*, 6-*H*) of the pyrrolidine ring, and one additional sp³-hybridized carbon atom which couples with the ethyl (**3A**) and phenyl (**4A**) group, respectively. In the 2-unsubstituted compound (**2A**), this CH₂-group forms a singlet at $\delta = 3.83$ ppm in CDCl₃. In contrast to thiazol-4(5*H*)-ones,^{4,8} neither the tautomeric thioisomünchnones (**2B**) – (**4B**), nor hydroxy isomers (**2C**) – (**4C**) were detectable by NMR spectroscopy, regardless of the solvent used. The C(2)-*H* protons are acidic and can be exchanged by deuterium on addition of D₂O to the solutions, respectively.

Scheme 1

As remarkable differences in the tautomerisations of thiazols and its reduced derivatives exist in the solid state and in solution,³ we performed an X-Ray analysis.⁹ Suitable single crystals of the 2-phenyl derivative (**4**) were obtained by slow evaporation of a concentrated solution in 2-propanol. The compound crystallized

monoclinic. The molecular structure and the crystallographic numbering are shown in Figure 1. The 6:7:5 pyrrolobenzodiazepine ring system adopts a twisted conformation. The C6-C7 bond distance (crystallographic numbering) is 132.21(17) pm which corresponds to a C(sp²)=C(sp²) double bond. This C=C-bond is twisted due to the helicity of the 6:7:5 ring system, so that the dihedral angles C5-C6-C7-N11 and N2-C6-C7-S8 are −173.40(12)° and 172.06(9)°, respectively. The thiazolidine ring adopts an envelope conformation. The sulfur atom is located above a plane defined by C9-C10-N11-C7, the dihedral angle of which is 1.44(15)°. The dihedral angles N11-C7-S8-C9 and S8-C9-C10-N11 were determined to be 31.81(9)° and 21.43(12)°, respectively. The phenyl ring is twisted by approximately 51° around the C9-C91-bond. Thus, (**4**) displays a different behaviour than thiazol-4-ones, the 4-hydroxy isomers of which predominate in the solid state.^{3,12} One hydrogen bonding is found between the CH-acidic C9-H and the C1=O carbonyl group of a neighbouring molecule. The elemental cell is presented in Figure 2.

Figure 1. Molecular drawing of **4A** (left); hydrogen bonding between two molecules (right).

Figure 2. Elemental cell of **4A**.

It is known that aromatizations of thiazolidines can be accomplished by addition to exocyclic double bonds.⁴ We therefore studied the behaviour of the new ring system towards acids, bases, and alkylating agents. The non-nucleophilic base 1,8-dimethylaminonaphthalene (proton sponge[®]) induced an immediate decomposition of **4** in THF to a complex mixture, whereas 4-dimethylaminopyridine (DMAP) and triethylamine, respectively, were not able to deprotonate this compound. On addition of NaOD/D₂O to a DMSO-d₆-solution of **4**, the resonance frequencies shift considerably upfield due to the formation of the

enolate (**6**). Thus, the proton in the *para*-position of the phenyl ring, which is overlapped in DMSO- d_6 by other signals at approximately $\delta = 7.39$ ppm, shifts to $\delta = 6.53$ ppm on addition of the base. The signal of C(2)-H at $\delta = 5.59$ ppm disappears in parallel with a shifting of the resonance frequency of C(2) at $\delta = 52.6$ ppm to $\delta = 72.6$ ppm in the ^{13}C NMR spectra on addition of the base (for numbering, cf. Scheme 1). Potassium *tert*-butoxide proved to be the most suited base to deprotonate the phenyl derivative (**4**) at C(2) in THF at -70°C to the corresponding enolate on a preparative scale. The enolate could be trapped by methyl iodide to form the 2-methyl-2-phenyl-substituted pyrrolobenzodiazepine (**7**) in 82% yield. HMBC-NMR spectroscopic experiments proved the couplings of the methyl protons with C(2), C(1)=O, and the phenyl group. Neither mesoion (**8**), which - in contrast to (**7**) - contained two aromatic rings, nor the *O*-methylated enol (**9**) were detected. Accordingly, no changes were moreover observable in the NMR spectra on addition of DCl, so that a protonation of the C(3a)=C(3b)-double bond could be excluded from consideration under these conditions.

Scheme 2.

ACKNOWLEDGEMENTS

Prof. Dr. E. Niecke, Prof. Dr. K. H. Dötz, and Prof. Dr. F. Vögtle, university of Bonn, are gratefully acknowledged for providing the X-ray crystallography facilities. The Deutsche Forschungsgemeinschaft (DFG) is gratefully acknowledged for financial support.

EXPERIMENTAL

General methods: The ^1H and ^{13}C NMR spectra were recorded on a Bruker ARX-400 and DPX-200 in DMSO- d_6 and CDCl_3 (400 and 200 MHz for ^1H NMR), respectively. The chemical shifts are reported in ppm relative to internal tetramethylsilane ($\delta = 0.00$ ppm). FT-IR spectra were obtained on a Bruker Vektor 22 in the range of 400 to 4000 cm^{-1} (2.5 % pellets in KBr). The GC-MS spectra were recorded on a GC Hewlett-Packard 5980, Serie II in combination with a MS Hewlett-Packard 5989 B, and on a Varian GC3900 with SAT2100T mass spectrometer. Solvents and reagents were obtained from commercial sources and used as received without further purification.

General procedure for the preparation of the benzocyclopentaazulene-1,7-diones (2 - 4). To a solution containing 0.232 g (1.0 mmol) of the monothiolactam (**1**) in 30 mL of anhydrous THF was added 1.2 mmol of the corresponding freshly distilled acetyl chloride. The mixture was stirred for 4 - 6 hours at rt under nitrogen and then quenched by addition of 20 mL of saturated NaHCO₃ solution. After extraction with 2 × 20 mL of chloroform, the combined organic layers were dried over Na₂SO₄, and the solvent was removed under reduced pressure. The crude residue was subjected to flash silica gel column chromatography using ethyl acetate / petroleum ether (1:4) as eluent to give yellow solids.

2-Methyl-2-phenyl-5,6-dihydro-4H-3-thia-6a,11b-diazabenzog[cyclopenta[e]azulene-1,7-dione (7).

To a solution of 0.174 g (0.50 mmol) of phenylthiazolidinone (**4**) in anhydrous THF (10 mL) was added 0.068 g (0.6 mmol) of potassium *tert*-butoxide portionwise at -70°C under nitrogen. The resulting mixture was stirred for additional 10 min at the same temperature. Methyl iodide (0.3 mL) was then added at -70°C , and the mixture was warmed to rt over a period of 10 min. Stirring was then continued for additional 30 min at rt. Then, the reaction was cautiously quenched with 10 mL of saturated NH_4Cl solution and extracted with 2×20 mL of chloroform. The combined organic layers were dried over Na_2SO_4 , and concentrated in *vacuo*. Purification by flash chromatography using ethyl acetate / petroleum ether (1:3) as eluent gave product (**7**) as a pale-yellow solid (0.148 g, 82%), mp $230 - 232^\circ\text{C}$ (acetonitrile); ^1H NMR (CDCl_3): $\delta = 7.97 - 8.02$ (m, 1H, 8-H), $7.50 - 7.60$ (m, 4H), $7.28 - 7.42$ (m, 4H), $3.83 - 3.90$ (m, 2H, 6-H), $2.52 - 2.78$ (m, 2H, 4-H), 2.03 (s, 3H, CH_3), $1.74 - 1.99$ (m, 2H, 5-H); ^{13}C NMR (CDCl_3): $\delta = 20.6$ (CH_2), 26.4 (CH_3), 31.1 (CH_2), 49.7 (CH_2), 60.4 , 123.9 , 126.1 , 126.7 , 127.9 , 128.0 , 128.6 , 132.7 , 133.1 , 138.7 , 140.5 , 165.2 (CO), 175.4 (CO); IR (KBr) 3070, 2965, 1715, 1690, 1630, 1489, 1454, 1389, 1328, 1197 cm^{-1} ; MS m/z (rel. Int.) 363 ($\text{M}^+ + 1$, 100), 333 (25), 301 (18), 226 (37), 195 (29), 159 (14), 104 (20), 79 (8); Anal. Calcd for $\text{C}_{21}\text{H}_{18}\text{N}_2\text{O}_2\text{S}$: C, 69.59; H, 5.01; N, 7.73. Found: C, 69.44; H, 4.98; N, 7.79.
