Abstract- Tautomerism of some bis(2-benzothiazolyl)methanes has been studied by  $^1\text{H}$  nuclear magnetic resonance, ultraviolet, and infrared spectroscopies using C-methyl and N-methyl derivatives as model compounds of the "CH" and "NH" fixed forms. X-Ray diffraction analysis of compound 6 shows that it corresponds to the Z-sE isomer b<sub>2</sub>. The presence of two 2-benzothiazolyl groups is necessary for the "NH" tautomer to be stable.

The tautomerism of heteroaromatic compounds has been so thoroughly studied that few problems remain unexplored.<sup>1</sup> One of them is the tautomerism of bis(heteroaryl)methanes, where only the case of bis-pyridyl, -quinolyl, and -benzoquinolylmethanes has received considerable attention, but more than twenty years ago.<sup>2</sup> We wish to report our results on the related bis(2-benzothiazolyl)methanes, a system of considerable interest both for its complexing abilities and for the derived cyanine dyes. Two tautomeric forms: CH (a) and NH (b) can be proposed for monosubstituted derivatives in the methane carbon atom of bis(2-benzothiazolyl)methanes, which can be considered as heterocyclic analogues of  $\beta$ -diketones. The tautomeric equilibrium in these series was first studied for the most simple derivatives: bis(2-benzothiazolyl)methane and 1,1-bis(2-benzothiazolyl)ethane.<sup>3</sup> We study here aryl- and heteroaryl-bis(2-benzothiazolyl)methanes 1-4 (Figure 1). As it occurred with the unsubstituted and C-methyl substituted bis(2-benzothiazolyl)methanes, the superimposition of CH/NH tautomerism and air-oxidation to carbinols,<sup>4</sup> precludes the usual treatment of tautomeric equilibria. Compounds 5 (type a structure, with Ar= Ph and R= CH<sub>3</sub>), 6 (type b structure, with

Ar= Ph and R= CH<sub>3</sub>), and 7 have also been included as reference models.

- 1 Ar= Ph, R= H  
2 Ar= p-NO<sub>2</sub>C<sub>6</sub>H<sub>4</sub>, R= H  
3 Ar= 2-pyridyl, R= H  
4 Ar= 2-benzothiazolyl, R= H

Figure 1

It must be remarked that the NH (b) forms can give place to three different isomers: E-sE,\* Z-sZ, and Z-sE (or E-sZ)<sup>3</sup> (Figure 2, R= H). Other structures which could be possible for the more complicated case of compounds 3 and 4, have not been depicted.

Figure 2

\* The old nomenclature s-cis/s-trans (single cis/single trans) for describing single bonds with double bond character has been replaced by the less ambiguous single E/single Z (sE/sZ) notation.<sup>5</sup>

The structural analysis has been undertaken by  $^1\text{H}$  nmr, ir, and uv spectroscopies and X-ray diffraction analysis of compound 6.

X-Ray study of compound 6.

Figure 3 shows a view of molecule 6 and the numbering for the crystallographic study. Bond lengths, and valence and torsion angles can be found in Table 1.

Figure 3.- A view of molecule 6 with atomic numbering.

The molecular rings are planar (mean torsion angles of the five rings A, B, C, D, and E are: 2.7(8), 1.5(6), 2.6(6), 3.0(7), and 2.7(8) $^\circ$  respectively) and the two benzothiazolyl groups are approximately in a plane (the dihedral angle between them is 2.2(1) $^\circ$ ). Similarly to the results<sup>3</sup> found for the simpler analogue 8, this structure corresponds to a Z-sE or  $b_2$  isomer. The mean torsion angle about the C10-C21 bond is 113.5(6) $^\circ$ . Since there are not significant differences between compounds 6 and 8, it must be concluded that the C-phenyl substituent exerts no influence on the conjugation of the bis(2-benzothiazolyl)methane system.

8

<sup>1</sup>H Nuclear magnetic resonance.

In spite of the great complexity, even at 300 MHz, of the <sup>1</sup>H nmr spectra of the compounds studied, the connectivities between protons and precise chemical shifts and coupling constants have been established by the combined use of bidimensional techniques and theoretical analysis of the spectra. The main problem was to distinguish between H4 and H7 benzothiazole protons. The two assignment criteria followed in our previous work<sup>3</sup> are also valid here ( $\delta_{H4} > \delta_{H7}$  in CDCl<sub>3</sub> solutions and  $\delta_{H7} > \delta_{H4}$  in DMSO-d<sub>6</sub> solutions, and  $J_{45} > J_{67}$ ).

The chemical shifts and coupling constant values in CDCl<sub>3</sub> and DMSO-d<sub>6</sub> are in Tables 2 and 3. We will first analyse the fixed a and b forms of model compounds 5 and 6.

Compound 5 exhibited the expected ABCD system which was interpreted following the criteria mentioned above. Compound 6 showed two ABCD systems. The chemical shifts of the system formed by H4'-H7' protons (specially the H4') appeared at higher field than those of the ABCD system formed by the H4-H7 protons. The first mentioned system was assigned to the benzothiazoline ring.

The CH forms of compounds 1-4 were characterized by the CH chemical shift at  $\delta = 6.3-6.6$  ppm in CDCl<sub>3</sub> and 6.7-7.1 ppm in DMSO-d<sub>6</sub>, while the NH tautomers gave broad signals (specially in DMSO-d<sub>6</sub>), and higher chemical shifts for H4-H7 protons. Autotropic prototropy interconverts isomers b<sub>2</sub> (Z-sE) and b<sub>4</sub> (E-sZ) (b<sub>2</sub>  $\leftrightarrow$  b<sub>4</sub>) and both isomers give an averaged ABCD system for the benzothiazole protons. Since b<sub>1</sub> isomers also give an averaged ABCD system, and the signal corresponding to the NH resonance was not observed in most cases, this method is not suitable for a general attribution to different b isomers.

Although the rapid oxidation of the NH forms<sup>4</sup> made impossible to determine any precise tautomeric constant, the changes observed in the relative populations of NH/CH forms in CDCl<sub>3</sub> and DMSO-d<sub>6</sub> were as follows. The spectrum of a freshly prepared CDCl<sub>3</sub> solution of 1, in which the NH tautomer was the predominant form, changed to a mixture of tautomers with relative populations NH/CH: 34%/66% after about ten minutes, and 23%/77% after a week, while a freshly prepared DMSO-d<sub>6</sub> solution showed a relative population NH/CH of 47%/53%. The different populations observed in both solvents are in accordance with the results discussed in our previous study,<sup>3</sup> indicating that the greater polarity of the DMSO-d<sub>6</sub> would stabilize the CH forms.

The spectrum of compound 2 in CDCl<sub>3</sub> solution corresponds to the NH tautomer, and the only observed change with time was its oxidation to the corresponding carbinol.<sup>4</sup> The spectrum in DMSO-d<sub>6</sub> solution was not very good due to the low solubility of 2 in this solvent, and only the CH tautomeric form could be detected, showing again the influence of the solvent polarity in the tautomeric equilibrium.

<sup>a</sup>Broad signals, only approximate values. <sup>b</sup>Not observable.

The  $\text{CDCl}_3$  solution of compound 3 revealed a tautomeric mixture ratio NH/CH of 56%/44%, while the  $\text{DMSO-d}_6$  solution showed the NH forms to be predominant (NH/CH: 61%/39%). The existence in this compound of the pyridine group, that must give place to new NH tautomeric forms, introduces a new structural factor which can not be easily interpreted.

We have obtained three solid samples for compound 4 with different spectroscopic properties. One of them corresponded, in  $\text{CDCl}_3$  solution, to the CH tautomer exclusively (4a). The  $\text{CDCl}_3$  solution of other sample, greenish-yellow in colour, showed two ABCD systems in 2:1 ratio together with a very low field signal at 15.7 ppm. These data are in agreement with the 4b<sub>1</sub> isomer (Figure 5).

Figure 5

The two benzothiazole rings which are bonded through the intramolecular  $\text{NH}\cdots\text{N}$  bond would give place to an averaged ABCD system, while the nonbonded benzothiazole ring would give a different ABCD system. The chemical shift of the NH signal (which was not visible in the previous NH forms studied) is in accordance with those described for  $\delta\text{OH}$  and  $\delta\text{NH}$  values of other intramolecular bonded dicarbonyl compounds<sup>6</sup> and bis(2-pyridyl)methane derivatives.<sup>2</sup> The  $\text{DMSO-d}_6$  spectrum of this tautomer showed very broad signals precluding a precise determination of the spectral parameters. The third solid sample is an approximate 1:1 mixture of CH and NH tautomers. The presence of a single ABCD system found for the NH tautomer, indicated a symmetrical structure assigned to 4b<sub>2</sub>  $\rightleftharpoons$  4b<sub>4</sub>, in which the third benzothiazole group is also implied.

Finally, the spectra of compound 7 in  $\text{CDCl}_3$  and  $\text{DMSO-d}_6$  solutions, corresponded to the CH tautomer exclusively and showed no change with time.

#### Infrared study.

Table 4 shows the characteristic ir bands of compounds 1-7 including some Raman data. The ir spectra of compounds 5 and 7 in the solid state showed the three characteristic benzothiazole bands<sup>3</sup> and no significant changes took place in  $\text{CDCl}_3$  solution. The same pattern was observed in the Raman spectra in the solid state. On the contrary, the ir spectra of compound 6 in the

solid and in  $\text{CDCl}_3$  solution were characterized by a very strong band at ca.  $1530\text{ cm}^{-1}$ , assigned to coupled vibrations in the planar  $\text{N}=\text{C}-\text{C}=\text{C}$  system, and a weak band at ca.  $1580\text{ cm}^{-1}$  assigned to the benzothiazole I band. The third expected weak benzothiazole band at ca.  $1555\text{ cm}^{-1}$  appeared overlapped by the first mentioned strong band. The above data are in accordance to those previously found for the CH and NH models respectively.<sup>3</sup>

The ir data of compound 1 in the solid state pointed out to an NH form (b) showing the strong absorption band assigned to the  $\text{N}=\text{C}-\text{C}=\text{C}$  system at  $1560\text{ cm}^{-1}$ . The absorption pattern was also similar to that found for the NH forms studied before.<sup>3</sup> The benzothiazole I band appeared in this compound at  $1595\text{ cm}^{-1}$  and, as it could be expected,<sup>3</sup> both bands were weak in the Raman spectrum of the solid. In  $\text{CDCl}_3$  solution, the intensity of the band at  $1565\text{ cm}^{-1}$  ( $\text{N}=\text{C}-\text{C}=\text{C}$  system) decreased with time. The presence of the CH form (detected by  $^1\text{H}$  nmr), could not be easily distinguished from the oxidation product, evidenced by the appearance of a broad absorption at about  $3420\text{ cm}^{-1}$  attributed to  $\nu\text{OH}$  stretching. In  $\text{DMSO-d}_6$ , the change to the CH form (and/or to the carbinol) took place quicker than in chloroform solution. It must be remarked that the  $\nu\text{NH}$  band of the NH tautomer could not be detected either in the solid nor in  $\text{CHCl}_3$  solution. However, in dilute  $\text{CCl}_4$  solution a broad weak absorption centered at about  $3050\text{ cm}^{-1}$  could be observed, this absorption being attributed to the presence of an intramolecularly bonded  $\text{NH}\cdots\text{N}$  group (b<sub>1</sub>).

The ir spectrum of compound 2 in the solid state was similar to that of compound 1 showing the characteristic  $\text{N}=\text{C}-\text{C}=\text{C}$  absorption at  $1555\text{ cm}^{-1}$  (very strong). The asymmetric stretching mode of the  $\text{NO}_2$  group appeared in this compound at  $1512\text{ cm}^{-1}$ . The same features were observed in a freshly prepared chloroform solution. As in compound 1, the intensity of the band at  $1555\text{ cm}^{-1}$  decreased with time. Although the spectrum in  $\text{CCl}_4$  has not been recorded due to solubility problems, we assume for this compound the b<sub>1</sub> structure.

The ir spectrum of compound 3 in the solid state was complicated in the  $1500\text{--}1600\text{ cm}^{-1}$  region by the presence of the pyridine bands. As in previous cases, the strong band at  $1545\text{ cm}^{-1}$  was assigned to the  $\text{N}=\text{C}-\text{C}=\text{C}$  coupled mode of the NH form. In  $\text{CDCl}_3$  and  $\text{DMSO-d}_6$  solutions, this band appeared at ca.  $1525\text{ cm}^{-1}$ . The shift towards lower frequencies observed by N-deuteration (in  $\text{CDCl}_3$ ) confirmed the assignment of this band to a complex coupled vibration of the enamine system of the NH forms. The intensity decreasing of this band compared with that found in the spectrum in KBr was attributed to an increasing of the CH tautomer already present in the solid. Moreover, the ir data showed that the NH form observed in solution is different from the original crystalline form. In  $\text{CCl}_4$ , results were similar to those of  $\text{CDCl}_3$  solution although a greater proportion of the NH form was observed. The spectrum of a very dilute  $\text{CCl}_4$  solution showed a broad complex absorption between  $3400$  and  $2400\text{ cm}^{-1}$  which was attributed to the presence of intramolecular  $\text{NH}\cdots\text{N}$  bonding. The three solid samples found for compound 4 gave different infrared spectra (Table 4). The KBr

Table 4.- Infrared and Raman characteristic frequencies ( $\text{cm}^{-1}$ ) for compounds 1-7.

<sup>a</sup>Not detected. <sup>b</sup>Abbreviations: s, strong; m, medium; w, weak; v, very; sh, shoulder; br, broad.<sup>c</sup>Possible contribution of ring  $\nu$ (C=C). <sup>d</sup>Very dilute solution. <sup>e</sup>Mixture of NH and CH tautomers.

spectrum of the greenish-yellow solid form presented the strong N=C-C=C band characteristic of the NH forms at  $1518\text{ cm}^{-1}$  and also showed another strong band at  $1473\text{ cm}^{-1}$  which was assigned to the benzothiazole III band of the third ring. In this case, a broad absorption at  $3200\text{--}2400\text{ cm}^{-1}$  was observed which was assigned to a NH stretching vibration. As this absorption was also observed in very dilute  $\text{CCl}_4$  solution, it can be deduced the existence of an intramolecular  $\text{NH}\cdots\text{N}$  bond ( $b_1$  isomer). Results in  $\text{CDCl}_3$  solution were similar and no noticeable changes were observed with time (four days). In  $\text{DMSO-d}_6$  solution (very low solubility) the  $b_1$  form was also observed. The spectrum of the sample characterized by  $^1\text{H}$  nmr as 4a showed in the solid state the three characteristic benzothiazole bands of a CH form (4a). In  $\text{CDCl}_3$  solution, the spectrum of this sample gradually changed to a NH form different from 4b<sub>1</sub> (see above), as it was revealed by the appearance of the enamine band at  $1555\text{ cm}^{-1}$  and the corresponding disappearance of the benzothiazole band at  $1503\text{ cm}^{-1}$ . This absorption pattern was similar to that observed for the third solid sample, assigned to a CH/NH mixture by  $^1\text{H}$  nmr. It must be remarked that the spectrum of this NH form in the solid state showed a complex broad absorption at about  $3200\text{--}2400\text{ cm}^{-1}$  which was also present in very dilute  $\text{CCl}_4$  solution, and in this case may be assigned to intramolecular  $\text{NH}\cdots\text{S}$  bonding.

#### Ultraviolet study.

Ultraviolet absorption data of compounds 1-7 are summarized in Table 5. Methanol was the solvent of choice, although chloroform solutions were used for compounds 2, 3, and 4 due to solubility reasons. Two different absorption patterns were observed for model compounds 5 and 6. Compound 5, a fixed a form, showed absorption maxima corresponding to the benzothiazole rings. Compound 6, a fixed b form, showed, together with the mentioned benzothiazole absorption bands, a strong absorption band at  $405\text{ nm}$ , according to the extended conjugation, and in the same way as it was observed for the b forms in the simpler derivatives previously studied.<sup>3</sup>

Compounds 1-4, except 4a, gave colored solutions with intense absorption bands at the  $\lambda = 390\text{--}430\text{ nm}$  region, similar to those found in the NH model compound 6. These solutions faded with time, specially when they were exposed to sunlight, and the final colorless solution showed no absorption in the above mentioned region, giving an absorption pattern analogous to the CH model compound 5, with absorption maxima below  $300\text{ nm}$ . This change, which could be attributed exclusively to the tautomeric displacement of NH to CH tautomers, corresponds however, as it was deduced from different experimental data, to the oxidation to carbinol derivatives, which give similar uv absorption patterns to that expected for the CH forms.<sup>4</sup>

Compounds 7 and 4a showed typical absorption bands of a CH tautomer. No changes were observed with time for compound 7, in agreement with the results obtained by other techniques, while the chloroform solution of 4a showed, after 24 hours, the absorption bands of NH tautomers at  $400\text{ nm}$ .

Table 5.- Ultraviolet data of compounds 1-7 in freshly prepared solutions.

Compound	Solvent <sup>a</sup>	$\lambda$ (nm)				
		(log $\epsilon$ )				
<u>1</u>	MeOH	205 (4.74)	268 (4.00)	394 (4.15)	414 (4.65)	435 (4.87)

<u>7</u>	MeOH	203 (4.74)	217 (4.61)	255 (4.03)	262 (3.98)	279 (3.48)

<sup>a</sup>The spectra in methanol and in chloroform were recorded in the ranges of 200-600 nm and 245-600 nm respectively.

### Conclusions.

A summary of the circumstantial evidence concerning the tautomerism of compounds 1-4 deduced from the different spectroscopic techniques, is given in Table 6. According to that, most compounds have been obtained as solid NH tautomers. Compound 4 has also been isolated as the CH tautomer. The greater polarity of DMSO-d<sub>6</sub> compared to CDCl<sub>3</sub> favours the breaking of the NH...N bonds, and the rapid transformation of NH to CH tautomers. Regarding the structure-tautomerism relationship, all compounds studied that have at least two benzothiazole groups are capable of tautomerism. Introduction of substituents at the methane carbon atom stabilizes the NH tautomer which is the form in the solid state although, in some cases, both tautomers have been isolated.

<sup>a</sup> Freshly prepared solutions. <sup>b</sup> The presumable presence of the a tautomers is not easily evidenced since benzothiazole bands are also present in the NH tautomer. <sup>c</sup> Not registered.

## EXPERIMENTAL

Crystallographic analysis of compound 6.

A crystal of about 0.1x0.1x0.3 mm was mounted along the long axis. The cell dimensions were refined from 39 general reflections with the Bragg angle  $\Theta_{\max}$  20° on an Enraf-Nonius CAD 4 diffractometer. Crystal data were: C<sub>22</sub>H<sub>16</sub>N<sub>2</sub>S<sub>2</sub>, monoclinic, P2<sub>1</sub>/n; a = 11.805(3), b = 8.896(3), c = 17.454(4) Å,  $\beta$  = 100.13(3)°, V = 1804.4(9) Å<sup>3</sup>, z = 4, D<sub>c</sub> = 1.3712 g/cm<sup>3</sup>. MoK $\alpha$ ,  $\lambda$  = 0.7107 Å, (graphite monochromator),  $\mu$  = 2.896 cm<sup>-1</sup>, F(000) = 776.

A total of 3916 independent reflections was measured in the range 2 <  $\Theta$  < 30° of which 1207 were considered as observed with the criterion I > 2  $\sigma$ (I). Two standard reflections were monitored every 100 min. No decomposition was detected during processing; corrections were made for Lorentz and polarization effects. Structure was solved by direct and Fourier methods and refined by full-matrix least-squares procedures, minimizing  $\sum w(\Delta F)^2$ , with isotropic temperature factors. An absorption correction following the DIFABS procedure<sup>7</sup> was applied to isotropically refined data, the maximum and minimum absorption factors being 0.994 and 0.681 respectively. Refinement was continued by full-matrix least-squares with anisotropic temperature factors. Hydrogen atoms were located from different synthesis and included with isotropic temperature factors. Final refinement led to R = 0.075 and R<sub>w</sub> = 0.073 with w from an empirical weighting scheme that fits so as to give no trends in  $\langle w \Delta^2 F \rangle$  vs. F<sub>o</sub> and  $\sin \Theta / \lambda$ ; <sup>8</sup>  $(\Delta / \sigma)_{\max}$  = 0.05 and residual electronic density in final difference map 0.20 eÅ<sup>-3</sup>, S = 0.866.

The atomic scattering factors were taken from International Tables for X-Ray Crystallography (1974).<sup>9</sup> The computation was performed on a Vax 11/750 with MULTAN 80,<sup>10</sup> XRAY 76,<sup>11</sup> and PARST<sup>12</sup>

programs.

$^1\text{H}$  Nmr spectra were obtained at 293 K on a Varian XL-300 spectrometer operating at 300 MHz, using  $\text{CDCl}_3$  and  $\text{DMSO}-d_6$  as solvents and TMS as internal standard. Typical acquisition parameters were: spectral width, 5 KHz; data size, 32 K; acquisition time, 3 s; and pulse width, 8  $\mu\text{s}$  ( $53^\circ$ ). In order to assign and determine chemical shifts and coupling constants, computer assisted analysis and 2D scalar shift correlated  $^1\text{H}$  nmr experiments were performed. The computer assisted analysis of four and eight spin systems were performed with the iterative program PANIC 81 on a Bruker Aspect 2000 computer. The eight spin systems were treated like two subsystems of four spins, using an additional routine for obtaining the experimental envelope. The error of the chemical shifts and coupling constants were estimated to be  $\pm 0.03$  Hz and  $\pm 0.05$  Hz respectively and the RMS value was 0.06. 2D experiments were carried out with the same spectrometer using the COSY-90 pulse sequence. The following parameters were used: number of increments, 128; pulse width, 13.5  $\mu\text{s}$ ; relaxation delay, 1 s; sweep width,  $\pm 200$  Hz in  $t_1$  and 400 in  $t_2$  and 256x256 transformed data points.

Ir spectra were recorded on a Perkin-Elmer 599B spectrophotometer. Indene and polystyrene were used for instrument calibration. All compounds were compressed into KBr pellets. Spectra in chloroform ( $\sim 0.05$  M;  $l = 0.02$  cm), and deuterated dimethyl sulfoxide solutions were also recorded. Spectra for very dilute carbon tetrachloride solutions (0.001 M) in the  $3600\text{--}2400$   $\text{cm}^{-1}$  region were also taken using 4 cm quartz cells.

Raman spectra were measured for some samples on a Jobin Yvon U 1000 spectrometer using argon radiation at 514.5 nm and krypton radiation at 647.1 nm. The samples were in the form of powder. Uv spectra were recorded on a Bausch and Lomb Spectronic 2000 spectrophotometer. The solutions were in the range of concentration of  $10^{-5}$  M.

Melting points are uncorrected and were measured on a Büchi capillary melting point apparatus. All compounds gave elemental analysis according to their structures.

The synthesis of compounds 1, 2, 3, and 4a is already reported.<sup>13</sup> The 4b<sub>4</sub> form of tris(2-benzothiazolyl)methane was obtained together with 4a when 4a was crystallized in benzene in the presence of catalytic amounts of acetic acid. The other samples were obtained as follows:

Tris(2-benzothiazolyl)methane, 4b<sub>1</sub>.

A solution of 0.01 mol (2.8 g) of bis(2-benzothiazolyl)methane<sup>14</sup> in 20 ml of dry DMF was added over a suspension of 0.01 mol (0.3 g of NaH 80%) of sodium hydride in 10 ml of dry DMF under  $\text{N}_2$  atmosphere and external cooling with an ice-water bath, after which, a solution of 0.005 mol (1.06 g) of 2-methylsulfonylbenzothiazole<sup>15</sup> in 5 ml of dry DMF was also added. The stirring was continued for further 4 h at room temperature and the final reaction mixture was filtered. The addition of water to the filtered solution afforded a precipitate which was filtered and

crystallized from benzene. The yield was 50%, mp 267-269 °C. Anal. Calcd for  $C_{22}H_{13}N_3S_3$ : C, 63.59; H, 3.15; N, 10.11 %. Found: C, 63.61; H, 3.50; N, 10.52 %.

1,1-Bis(2-benzothiazolyl)-1-phenylethane, 5.

Butyllithium (3.75 ml of 1.6 M solution) was added over a solution of 0.005 mol (1.79 g) of 1 in 60 ml of THF at -10 °C under  $N_2$  atmosphere, followed by addition of 0.006 mol (0.852 g) of methyl iodide in THF (10 ml). The reaction mixture was kept at room temperature for 4 h and then refluxed 18 h. The mixture was poured onto ice-water, extracted with ether, and the ethereal layers were dried over anhydrous sodium sulfate and concentrated under "vacuum". The crude product obtained was purified by column chromatography over aluminium oxide with hexane-chloroform (10:3) as eluent. Compound 5 was obtained in 31 % yield, mp 114-117 °C (ethanol). Anal. Calcd for  $C_{22}H_{16}N_2S_2$ : C, 70.93; H, 4.33; N, 7.52 %. Found: C, 71.17; H, 4.68; N, 7.81 %.

Phenyl-2-benzothiazolyl-3-methyl-2,3-dihydro-2-benzothiazolilidenemethane, 6.

A mixture of 0.01 mol (3.58 g) of 1 and 0.01 mol (1.51 ml) of methyl p-toluenesulfonate was heated at 180 °C for 3 h. The solid residue was treated with chloroform and water, and the organic layer was dried over anhydrous magnesium sulfate and concentrated under "vacuum". The treatment of the residue with ethanol and ether gave a solid which was filtered and identified as 6, with a yield of 19 %, mp 207-209 °C (ethanol). Anal. Calcd for  $C_{22}H_{16}N_2S_2$ : C, 70.93; H, 4.33; N, 7.52 %. Found: C, 70.82; H, 4.13; N, 7.47 %.

2-Benzothiazolyl-diphenylmethane, 7.

To a solution of 0.03 mol (3.75 g) of o-aminothiophenol and 43 g of polyphosphate ester<sup>16</sup> in 50 ml of chloroform (dried over phosphorous pentoxide), 0.045 mol (9.54 g) of diphenylacetic acid was added, and the whole was refluxed for 30 min. The mixture reaction was concentrated and neutralized with a cold aqueous solution of sodium bicarbonate. The crude solid thus obtained was filtered and extracted with petroleum ether to give 7 after evaporation. Yield, 64 %, mp 88-90 °C (ethanol), (lit.<sup>17</sup> mp 89-91 °C from methanol). Anal. Calcd for  $C_{20}H_{15}NS$ : C, 79.70; H, 5.02; N, 4.65 %. Found: C, 79.57; H, 5.00; N, 4.62 %.
