A NEW SYNTHESIS OF 5-NITROFURYLETHYLENE COMPOUNDS

Jaroslav Kováč

Department of Organic Chemistry, Slovak Technical University, 880 37 Bratislava, Jánšká 1, Czechoslovakia

The methods of synthesis known up to this date of 5-nitrofuryl-ethylene derivatives give possibilities of preparing only some types of these compounds. The new found ways in this area enabled to synthesise new type of 5-nitrofuryl-ethylene compounds.

The first way is based on the use of the acidic hydrogens of some nitrofuryl derivatives in the condensation reactions with carbonyl compounds.

This method is suitable for preparing three and foursubstituted 5-nitrofuryl-ethylene derivatives. The modified Horner-Wittig reaction on suitable ketone was used in the case, when X was an electrondonating group.

The second way is more common and give possibilities to prepare unknown compound of 5-nitrofuryl-ethylene series. This method is based on the use of 5-nitrofurylvinylbromide (I) in the nucleophilic vinylic substitution reaction, where the reagents are compounds containing a free electron pair

nitrogen heterocycles and so on

The elimination of HBr goes by the action of strong bases on I and the 5-nitrofurylacetylene arises.

The use of 5-nitrofurylvinylammonium salts is more advantageous while the reaction proceeds in polar solvent and this compound reacts with more reagents than compound I.

The enamines of 5-nitrofuryl-ethylene type are the potential source for preparation of derivatives of unknown 5-nitrofuryl-acetaldehyde

RINGSCHLUSSREAKTIONEN AN SELENOCARBONAMID-DERIVATIVEN ZU 1,3-SELENAZOLEN, 1,3,4-SELENAJAZINEN UND 1,3,4-SELENAJAZOLEN

E. Bulka

Wissenschaftsbereich Organische Chemie der Sektion Chemie der Ernst-Moritz-Arndt-Universität DDR - 22 Greifswald, Soldmannstr. 16

Selenazoles are the selenium analogues of thiazoles, and although the first derivatives of 1,3-selenazole were prepared by Hofmann as early as 1889, only a few publications on this subject have appeared in the literature until now. Hofmann was a student of Hantzsch's and transferred his thiazole synthesis to the selenazoles. This most useful and versatile of all the thiazole syntheses is the reaction of an α -halo ketone or aldehyde with a thiourea. For his purpose Hofmann used selenourea instead of thiourea. Even nowadays this method is still the most usual one. It permits a wide variety by choosing suitable reaction partners as to be seen in formula 1.

The selenoureas, needed for condensation, can usually be prepared by addition of hydrogen selenide to a solution of the corresponding cyanamides or carbodilimides. They can be less dangerously and quite smoothly synthesized according to Douglas via the isoselenocyanates by the alkaline hydrolysis of the corresponding acyl-substituted selenoureas (formula 2).

2-Hydrazinoselenazoles have been prepared by the use of selenosemicarbazide as selenocarbonamide. Starting from acetone selenosemicarbazone one can prepare the 2-isopropylidenehydrazinoselenazoles in a smooth reaction by condensation with α -halocarbonyl compounds. Their careful acidic hydrolysis leads to the free 2-hydrazino-selenazoles (formula 3).

On the other hand, the α -halocarbonyl component offers the possibility of variation too. For instance, α -halocarboxylic acids, or rather their esters, form derivatives of 4-oxoselenazoline (formula 4).

First investigations on the reactivity of the 1,3-selenazoles were undertaken by Haginiwa. He came to the conclusion that the 5-position of selenazoles is slightly reactive towards electrophilic substitution. This reactivity is still further increased by substituents in the 2-position, which can exert the +M-effect. We found during our investigations multiple nitration depending on the conditions of the reaction and the substrate, whereas Haginiwa only described the formation of the 5-nitro derivatives. Thus, the 2-benzamino-4-ary(alkyl)selenazoles form the corresponding 5-nitro derivatives under mild conditions using the nitrate/sulfuric acid method. The use of cold mixed nitric and sulfuric acids also effects the phenyl groups which may be present, leading to dinitro or trinitro compounds (formula 5).

The bromination is not as complicated as the nitration. Bromination was carried out in several solvents and with various amounts of bromine. In spite of the great variation in conditions, monobromo derivatives containing the bromine atom in the 5-position are always formed (formula 6).

The high reactivity of the 5-position in 1,3-selenazoles towards electrophilic substitution was also to be observed on azo coupling. By reacting molar quantities of an aqueous solution of a diazonium salt with an ethanolic solution of a 2-arylamino-selenazole, for instance, the corresponding 2-arylamino-5-azo-selenazole is formed in a smooth reaction (formula 7).

If the free selenosemicarbazide is used instead of selenosemicarbazones for the condensation with 2-halocarbonyl compounds, as mentioned above, the reaction will be quite different. The sole final product that can be isolated in neutral as well as acidic solution is the 2-p-chloroanilino-5-phenyl-1,3,4-thiadiazine, as illustrated by the 4-p-chlorophenylselenosemicarbazide. In the mother liquor there are, however, traces of the 2-hydrozonselenazoline. The third possible isomer, the 3-amino-2-iminoselenazoline, could not be detected in any case (formula 8).

Starting from selenosemicarbazides one can also arrive at the third substance type, the 1,3,4-selenadiazoles. The first compounds of this type were obtained by Stollé and Gutmann in 1904 on reaction of *N,N'*-diacylhydrazines with phosphorus pentaselenide. Lalezari and Shafiee synthesized 2-amino-1,3,4-selenadiazoles from selenosemicarbazide and carboxylic acids in the presence of phosphorus oxychloride. They obtained the free 2-amino compounds by hydrolysing the initially formed 2-acylamino derivatives (formula 9).

We found in connection with the synthesis of substituted selenosemicarbazides that the cyclisation of the acyl derivatives under suitable conditions is a generally applicable method for obtaining the 2-amino-1,3,4-selenadiazoles. The 2-arylamino-1,3,4-selenadiazoles could be obtained in the same way by cyclisation of the 1-acyl-4-arylselenosemicarbazides (formula 10).
