Biologically active natural products containing the pyrrolidine ring have been synthesized using 4-O-benzyl-2,3-O-bis(methoxymethyl)-L-threose (1), readily available from L-tartaric acid. The key feature of the synthesis is 1,2-asymmetric induction of chiral α -(methoxymethyl)oxy carbonyl compounds based on α -chelation control.

A diastereomeric mixture of the alcohols 2, derived from 1, was subjected to the Mitsunobu reaction, affording a 1:1 mixture of the *syn* and *anti* phthalimides 3. The less polar component, *syn*-3, was converted to the aldehyde 4 which on treatment with the Grignard reagent exclusively gave the *threo* alcohol 5. Transformation of 5 into (+)-codonopsinine (6) was achieved in 5 steps which established the absolute configuration of the natural product to be 2S,2R,4R,5R.

On the other hand, the L-*threo*-fructose derivative 7, prepared by debenzylation of 1, was converted to the ketone 8, which afforded *erythro*-9 as a virtually sole product on reduction with zinc borohydride. Further steps resulted in the formation of deacetyl anisomycin which after N-protection underwent selective silylation to provide 10. The subsequent sequence involving acetylation-deprotection (two times) yielded optically pure (-)-anisomycin (11).
