

THE ACID-CATALYZED OXIDO-REDUCTION OF SPIROKETALS. EVIDENCE FOR
STEREOELECTRONIC CONTROL IN HYDRIDE TRANSFER TO CYCLIC OXENIUM IONS[†]

Pierre Deslongchamps*, Daryl D. Rowan, and Normand Pothier

Tricyclic spiroketal 1 undergoes an acid-catalyzed oxidation-reduction reaction which yields equatorial bicyclic ether aldehyde 5 specifically. Similarly, spiroketals 2, 3, and 4 gave equatorial bicyclic ether ketone 12. These results are interpreted by invoking an internal hydride transfer from an alcohol function to a cyclic oxenium ion which takes place with stereo-electronic control.

We have recently shown that the 1,7-dioxaspiro[5.5]undecane and its derivatives provide a very convenient system for the study of stereoelectronic effects (anomeric and exo-anomeric effects) in the acetal function (1, 2). In the course of that study, we observed that these spiroketals undergo an acid-catalyzed oxidation-reduction reaction. We wish to report that investigation.

We have studied the tricyclic spiroketal 1¹ and the three isomeric methyltricyclic spiroketals 2¹, 3¹, 4¹ (Scheme 1).

Treatment of tricyclic spiroketal 1 with hydrogen bromide in ether-pentane gave stereo-specifically the bicyclic ether aldehyde 5² (=40% yield). Reduction (LiAlH₄, ether) of compound 5 gave the corresponding alcohol 6² which was further characterized by formation of the acetate derivative 7². The structure and the stereochemistry of bicyclic ether alcohol 6 was established by comparison with an authentic sample.

Authentic samples of compound 6 and its isomer 8 were obtained from the monocyclic ketone mesylate 9³. Reduction of compound 9 (NaBH₄, CH₃OH) gave a mixture of the isomeric alcohols 10²

[†] We are pleased to dedicate this article to Professor Tetsuji Kametani.

¹ The preparation of this compound is described in reference 1.

² All new compounds gave satisfactory spectroscopic data. High resolution ms were obtained for alcohols 6 and 8, to which other new compounds are chemically converted.

³ The preparation of compound 9 is described in reference 3.

which was transformed (KH, THF) into the isomeric mixture of THP-bicyclic ethers 11². Acid hydrolysis of the mixture 11 gave the bicyclic ether alcohols 6² and 8² which were separated by chromatography. The relative stereochemistry of isomers 6 and 8 was established by carbon nuclear

magnetic resonance spectroscopy. In particular, the carbons 2, 4, and 6, γ , α , and γ respectively to C₁₁ of the side chain, show shieldings of 7.7, 4.8, and 5.8 ppm (4) on passing from 6 to its axial epimer 8.

We have also observed that the tricyclic spiroketal 2 or its isomer 3 gave the bicyclic ether methyl ketone 12² ($\approx 100\%$ yield) with aqueous hydrochloric acid under reflux conditions. Similarly, treatment of the isomer 4 (which is interconvertible with 3 under mild acidic conditions (1)) gave compound 12 upon reflux with aqueous hydrochloric acid. The structure and the stereochemistry of the bicyclic ether methyl ketone 12 was rigorously established by its conversion into the bicyclic ether alcohol 6 (NaOBr, NaOH; LiAlH₄).

The acid-catalyzed oxido-reduction reactions described above can be readily explained by the opening of the spiroketals giving an hydroxy bicyclic oxenium ion intermediate such as 13 which undergoes an internal hydride transfer to yield the bicyclic ether 6 or 12. This mechanism is very similar to the one proposed by Woodward, Sondheimer, and Mazur (5) to explain the acid-catalyzed interconversion of the normal and the *iso* sapogenins. Their proposal was also supported by strong experimental evidence.

The stereospecific formation of the equatorial bicyclic ethers 6 and 12 can be explained if stereoelectronic effects (6) are taken into consideration. If we accept that the hydride transfer will take place with minimum energy only when the intermediate oxenium ion can develop an electron pair which will become antiperiplanar to the newly formed C-H bond in the final product, the above results can be easily rationalized.

It can be readily seen that the β -attack on 13, i.e. 14 $\rightarrow$ 6 or 12 can occur with stereoelectronic control whereas the α -attack on 13 (i.e. 15) cannot yield directly the axial bicyclic ether in its more stable conformation 17. The α -attack on 13 must first give conformer 16 having its ring B twisted in order to fulfill the orbital alignment requirement. Conformer 16 would then give the most stable conformation 17. The transformation 15 $\rightarrow$ 16 $\rightarrow$ 17 requires more energy than 14 $\rightarrow$ 6 (or 12). Consequently, the formation of 17 cannot compete with the formation of equatorial bicyclic ether 6 or 12.
