In the course of our seeking a novel synthetic method using a heterocycle, we investigated a new annelation reaction using 4H-pyran-4-one (γ -pyrone) derivative as a making 1,5-diketone precauser.

The first foundmental work, which γ -pyrone could change to a 1,5-diketone derivative was converted to 3-methylthio-3-hexen-1,5-dione followed by desulfurization and reduction.

The next problem i.e., the selective alkylation at the 2-methyl position of γ -pyrone, was resolved by using 2-methyl-6-p-tosylmethyl-4H-pyran-4-one as the alkylating substrate.

After the clarification of these two problems we coupled I with 2-methyl-6-(1-p-tosyl-2-iodoethyl)-4H-pyran-4-one to give II. The compound II was converted to III followed by desulfurization and reduction to give 1,5-diketone derivative. This was cyclized and aromatization to afford D-homoesterone.
