5'-Deoxy-5'-adenosineacetic acid (5'-AAA) (1), which was first synthesized by Follmann¹⁾, is known as a useful model nucleotide of 5'-AMP. For the biological and physicochemical interests, we synthesized 3'-Uridinyl 5'-deoxy-5'-adenosineacetate (5) [by condensation of a 2',3'-O-ethoxymethylene-5'-AAA (2) with 2'-O-benzyl-5'-O-monomethoxytrityluridine (3) followed by hydrogenolysis in 80% acetic acid] and N-(2'-deoxy-2'-uridinyl)-5'-deoxy-5'-adenosineacetamide (6) [by condensation of (1) with 2'-amino-2'-deoxy-5'-O-monomethoxytrityluridine (4) followed by treatment with 80% acetic acid]. The spectroscopical evidences for the structure of these dinucleotide-like compounds, which have a carboxy ester or an amide linkages instead of a phosphate group, are given.
