**Abstract** – Amphirionins-3 (**1**) and -6 (**2**) have been isolated from the marine dinoflagellate *Amphidinium* species. The structures were elucidated by detail analyses of the spectroscopic data, and chemical conversions. Compounds **1** and **2** exhibited moderate cytotoxic activity against human cervix adenocarcinoma HeLa cells.

Marine dinoflagellates of the genus *Amphidinium* are well known to produce polyketide-like metabolites.<sup>1,2</sup> Cytotoxic macrolides<sup>3,4</sup> and polyhydroxy long-chain polyketide compounds<sup>5,6</sup> have been isolated from the marine symbiotic and free-swimming *Amphidinium* species. On the other hand, certain low-polarity polyketide compounds with a relatively-small molecule size, represented by amphidinins<sup>7,8</sup> and amphidinoketides,<sup>9</sup> constitute the third class of *Amphidinium* dinoflagellates metabolites. Recently, we have also discovered a series of new polyketides, amphirionins-2,<sup>10</sup> -4,<sup>11</sup> and -5,<sup>12,13</sup> from the marine benthic dinoflagellate *Amphidinium* species collected off Iriomote Island, Okinawa Prefecture, Japan. Our continuing search for new polyketides from laboratory-cultured marine dinoflagellate *Amphidinium* species<sup>14-16</sup> resulted in the isolation of two new linear polyketides, amphirionins-3 (**1**) and -6 (**2**), from the benthic dinoflagellate *Amphidinium* species (strains KCA09057 and KCA09056). The structures were elucidated by detailed analyses of the spectroscopic data and chemical conversions. The absolute

<sup>a</sup>OH signals were observed at  $\delta_{\text{H}}$  4.88 (1H, t,  $J = 2.2$  Hz), 4.76 (1H, brs), and 2.36 (1H, brs). <sup>b</sup>2H. <sup>c</sup>3H.

Figure 1. Selected 2D NMR correlations for amphirionin-3 (**1**)

The gross structure of **1** was reminiscent of the amphidin A<sup>7,17</sup> (**4**) structure. Therefore, the elucidation of the relative stereochemistry of **1** was performed by comparing the  $^1\text{H}$  and  $^{13}\text{C}$  NMR chemical shifts for **1** with those obtained for amphidin A (**4**). Figure 2 illustrates  $^1\text{H}$  and  $^{13}\text{C}$  chemical shift differences [ $\Delta\delta$  (in ppm) =  $\delta$  for **1** –  $\delta$  for **4**] for C-1–C-12 and the four branched  $\text{C}_1$  moieties at C-6, C-7, C-9, and C-11. The  $^{13}\text{C}$  chemical shift differences for C-1–C-7 and the C-20 methyl were negligible ( $\leq 0.3$  ppm),

indicating that the relative stereochemistry for C-2, C-4, and C-6 of **1** were *R\**, *R\**, and *S\**-configurations, respectively, i.e., the same as those of **4**.<sup>17</sup> The relative configuration for the tetrahydrofuran ring at C-9–C-12 was elucidated by analysis of the NOESY correlations observed for **1** in CDCl<sub>3</sub> (Figure. 3). NOESY correlations for H-6/H-8a, H-8a/H<sub>3</sub>-20, and H-8b/H<sub>3</sub>-18 suggested the 6*S\**- and 9*R\**-relations. Thus, total six stereocenters in **1** were established to have the same relative configurations as those of **4**.

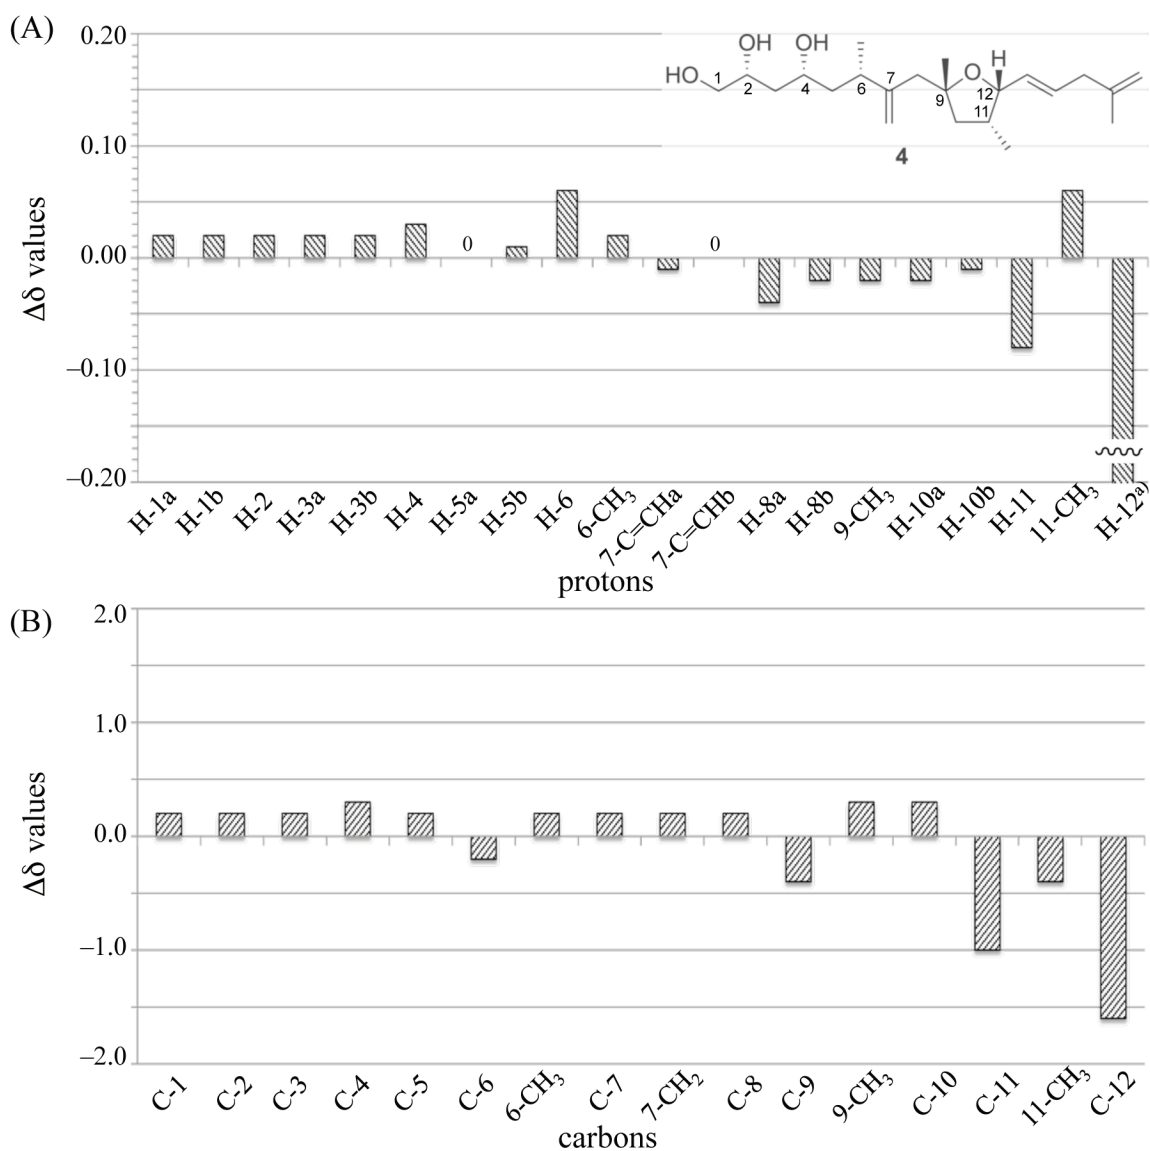

Figure 2. Differences between NMR chemical shifts of amphirionins-3 (**1**) and amphidin A (**4**) in CDCl<sub>3</sub>. (A)  $\Delta\delta_H$  (in ppm) =  $\delta_H$  of **1** -  $\delta_H$  of **4**. (B)  $\Delta\delta_C$  (in ppm) =  $\delta_C$  of **1** -  $\delta_C$  of **4**. “a” and “b” for geminal proton pairs denoted low- and high-field resonances, respectively. a)  $\Delta\delta_H$  values for H-12 was -0.43.

Figure 3. Stereostructure for the C-4–C-12 portion in amphirionin-3 (**1**).

Arrows show the NOESY correlations in  $\text{CDCl}_3$ .

The molecular formula,  $\text{C}_{20}\text{H}_{38}\text{O}_4$ , of amphirionin-6 (**2**) was revealed by [ESIMS  $m/z$  365.26675 ( $\text{M}+\text{Na}$ )<sup>+</sup>,  $\Delta$  -0.03 mmu]. The  $^{13}\text{C}$  NMR data of **2** in  $\text{C}_6\text{D}_6$  presented a total of 20 carbon resonances, arising from an  $\text{sp}^2$  quaternary carbon,  $\text{sp}^2$  methylene, oxygenated  $\text{sp}^3$  quaternary carbon, five  $\text{sp}^3$  methines, eight  $\text{sp}^3$  methylenes, and four methyls. The planar structure of **2** elucidated on the basis of detailed NMR studies in  $\text{C}_6\text{D}_6$  was established to be a 14,15-dihydro derivative of amphirionin-3 (**1**). The reduction of **1** using palladium–charcoal under hydrogen atmosphere afforded **2**, thus indicating that **2** possessed identical stereochemistry to that of **1**. The absolute stereochemistry of C-4 in **2** was assigned as *R* on the basis of the CD spectrum of the tribenzoate derivative (**3**) of **2**, where the negative and positive Cotton effects were detected at 233 ( $\Delta\epsilon$  -5.61) and 220 (+2.60) nm, respectively.<sup>18</sup> Therefore, the absolute configurations of the six chiral centers of **1** and **2** were concluded to be 2*R*, 4*R*, 6*S*, 9*R*, 11*R*, and 12*R*.

Two new low-polarity polyketide compounds, amphirionins-3 (**1**) and -6 (**2**), are congeners of amphidinins A<sup>7</sup> and G.<sup>8</sup> Compounds **1** and **2** exhibited medium growth inhibition against human cervix adenocarcinoma HeLa cells with equal  $\text{IC}_{50}$  values of 30  $\mu\text{M}$ , indicating that the double bond at C-14 do not affect the cytotoxic activity.

## EXPERIMENTAL

**General information.** The optical rotations were measured on a JASCO DIP-370 and P-2300 polarimeters, IR spectra were recorded on a JASCO FT/IR-5300 spectrophotometer. The CD spectrum was obtained on a JASCO J-1500 spectropolarimeter. NMR data for **1** were recorded on an Agilent NMR400WB spectrometer equipped with a PFG-HX or XH nanoprobe. NMR spectra of **2** were measured on a Bruker AMX-500 spectrometer using 2.5–mm microcells (Shigemi Co. Ltd.). The  $^1\text{H}$  and  $^{13}\text{C}$  chemical shifts in  $\text{CDCl}_3$  were reported in ppm relative to the residual signals of  $\text{CDCl}_3$  ( $\delta_{\text{H}}$  7.16 and  $\delta_{\text{C}}$  77.16). Chemical shifts in  $\text{C}_6\text{D}_6$  are reported in ppm with reference to the residual proton and carbon signals ( $\delta_{\text{H}}$  7.20 and  $\delta_{\text{C}}$  128.0) of the solvent. ESIMS spectra were obtained on an LTQ Orbitrap XL and Exactive spectrometers (ThermoFisher Scientific Inc.).

**Cultivation and Isolation.** A seawater medium was added to benthic sea sand samples collected off Iriomote Island, Japan, and the mixture was incubated for several weeks. Two dinoflagellate strain KCA09056 and KCA09057 were isolated monoclally by micropipetting. The voucher specimens were deposited at the Center for Advanced Marine Core Research, Kochi University. The KCA09057 strain was cultured at 27–29 °C for two weeks in seawater medium enriched with 1% PES supplement, with light and dark cycles of 16 h and 8 h, respectively. The dried algal cells (53.54 g from 2,000 L culture) were extracted with MeOH–toluene (3:1), and partitioned between toluene and H<sub>2</sub>O. The toluene-soluble materials (2.94 g) were subjected to silica gel column chromatography using a gradient elution of 0–5% MeOH in CHCl<sub>3</sub>. The fraction eluted with CHCl<sub>3</sub>–MeOH (95:5) was then chromatographed on C<sub>18</sub> (MeCN–H<sub>2</sub>O, 7:3) and amino silica gel (hexane–EtOAc, 1:1–1:4) columns. The fraction eluted with hexane–EtOAc (1:4) was separated by C<sub>18</sub> HPLC [YMC-Pack Pro C<sub>18</sub>, 10 mm × 250 mm; eluent, MeCN–H<sub>2</sub>O (70:30); flow rate, 2 mL/min; UV detection at 230 nm] to afford amphirionin-3 (**1**, 1.0 mg, 0.002%). The strain KCA09056 was cultured under the above-described conditions. The harvested cells (15.3 g, from 400 L culture) were extracted with MeOH–toluene (3:1), and the extract was partitioned between toluene and water. The toluene-soluble fractions (2 g) were subjected to SiO<sub>2</sub> column chromatography using a stepwise elution of CHCl<sub>3</sub> and CHCl<sub>3</sub>–MeOH (98:2). The fraction eluted with (CHCl<sub>3</sub>–MeOH, 98:2) was chromatographed successively on a C<sub>18</sub> column (MeCN–H<sub>2</sub>O, 7:3) followed by C<sub>18</sub> HPLC [YMC-Pack Pro C<sub>18</sub>, 5 μm, YMC Co., Ltd., 10 x 250 mm; eluent, MeCN–H<sub>2</sub>O (60:40); flow rate, 2 mL/min; UV detection at 210 nm] to afford amphirionin-6 (**2**, 4.3 mg, 0.028%).

**Amphirionin-3 (1):** colorless oil;  $[\alpha]_D^{20}$  -26 (*c* 0.1, CHCl<sub>3</sub>); IR (neat)  $\nu_{\max}$  3450 (broad) and 2980 cm<sup>-1</sup>; <sup>1</sup>H and <sup>13</sup>C NMR data (CDCl<sub>3</sub> and C<sub>6</sub>D<sub>6</sub>, see Table 1); HRESIMS *m/z* 363.25026 [calcd for C<sub>20</sub>H<sub>36</sub>O<sub>4</sub>Na, (M+Na)<sup>+</sup>: 363.25113].
