**Abstract** – Thermal decomposition of *N*-alkylated 2-aminobenzophenones **1a-d** was studied at 400-560 °C, using calcium oxide as catalyst. The reactions yielded both 5- and 6-membered heterocyclic compounds. The *N*-methylated-2-aminobenzophenones **1a-b** decomposed at 400-560 °C to give 2-phenylindole **2** (47% at 500 °C from **1b**), acridine **4** and phenanthridine **5**, while the *N*-benzylated-2-aminobenzophenones **1c-d** decomposed at 400-560 °C to give 2,3-diphenylindole **3** (33% at 450 °C and 400 °C from **1c** and **1d**, respectively), acridine **4** and phenanthridine **5**.

Thermal decomposition reaction is an interesting reaction to investigate since it can give a variety of products – some expected while others are unexpected, interesting, and useful in other fields of science.<sup>1</sup> The formation of the different products may even occur via different reaction mechanisms. Several literatures report on the synthesis of carbazole by heating 2-nitrobiphenyl with deoxygenating agent such as iron(II) oxalate<sup>2</sup> or triethyl phosphite.<sup>3</sup> Krbecek and Takimoto reported that thermal decomposition of *o*-substituted phenylazides, whenever possible, generally leads to 5-membered-ring structures.<sup>4</sup> The formation of the cyclic products from the nitro- or azido-compounds were found to occur via the nitrene intermediate.<sup>5</sup> Primary arylamines were also found to undergo dehydrocyclization reactions at 400-700 °C to yield carbazoles and phenoxazine, as reported by Horaguchi, *et al.*<sup>6</sup> On the other hand, Tsang, *et al* reported the formation of *N*-substituted carbazoles from substituted arylamines by heating at 120 °C in the presence of either palladium or copper catalyst.<sup>7</sup>

In our laboratory, we have studied thermal decomposition of a number of aromatic amines by subjecting them to high temperatures using specialized apparatus in the presence of calcium oxide catalyst (Scheme

1). Thermal decomposition of 2-aminobiphenyl yielded carbazole (80% at 560 °C)<sup>8</sup> while the *N*-alkylated-2-aminobiphenyls gave several products: carbazole, methyl carbazole, phenanthridine and phenanthrene.<sup>9</sup> Thermal decomposition of *N*-alkyl-2-benzylanilines yielded acridine, anthracene, 2-phenylindole and 2,3-diphenylindole while thermal decomposition of *N*-alkyl-*N'*-phenyl-*o*-phenylenediamines yielded acridine, phenazine and 2-phenylbenzimidazole.<sup>10</sup> We have proposed the formation of all these products to occur via nucleophilic substitution on the aromatic a rather rare reaction mechanism, except for the phenylindoles and the benzimidazole which were formed by the reaction of either a carbanion or amide ion with an imine carbon.

In this paper, we report the results of thermal decomposition of *N*-alkylated-2-aminobenzophenones and compared these with our previous studies.

**Scheme 1.** Thermal decomposition reactions of aromatic amines

The starting materials used were prepared either by methylating or benzylating 2-aminobenzophenone as described in the Experimental Section. When heated at 400-560 °C in the presence of calcium oxide catalyst, 2-methylaminobenzophenone **1a** yielded 2-phenylindole **2** (15-32%) with highest yield obtained at 400 °C (32%), acridine **4** (3-17%) and phenanthridine **5** (3-10%) (Table 1, Entries 1-4). With 2-dimethylaminobenzophenone **1b**, the products formed by thermal decomposition at 400-500 °C were 2-phenylindole **2** (38-47%) with highest yield obtained at 500 °C (47%), acridine **4** (4-6%) and phenanthridine **5** (11-21%) (Table 1, Entries 5-7). While thermal decomposition at 450-600 °C of

2-aminobenzophenone<sup>8</sup> yielded acridine (3-7%), acridone (21-32%) and carbazole (2-14%), the *N*-methylated-2-aminobenzophenone produced other products, 2-phenylindole **2** and phenanthridine **5**, aside from acridine **4** (Scheme 2).

No carbazole and acridone were detected from the thermal decomposition of 2-methylaminobenzophenone **1a** and 2-dimethylaminobenzophenone **1b**. When 2-benzylaminobenzophenone **1c** was heated at 400-500 °C in the presence of calcium oxide catalyst, 2,3-diphenylindole **3** (28-33%) with

**Scheme 2.** Thermal decomposition reactions of *N*-alkylated-2-aminobenzophenones **1a-d**

highest yield obtained at 450 °C (33%), acridine **4** (3-5%) and phenanthridine **5** (7-11%) were produced (Table 2, Entries 1-3). 2-Dibenzylaminobenzophenone **1d** also yielded 2,3-diphenylindole **3** (17-33%)

**Scheme 3.** Proposed mechanism for the formation of 2-phenylindole and 2,3-diphenylindole from thermal decomposition of *N*-alkylated-2-aminobenzophenones (**1a-d**)

with highest yield obtained at 400 °C (33%), acridine **4** (8-16%) and phenanthridine **5** (4-6%) (Table 2, Entries 4-7), when heated at 400-560 °C in the presence of calcium oxide catalyst (Scheme 2). Again, no acridone and carbazole were detected but instead another product, 2,3-diphenylindole **3**, was identified. The formation of 2-phenylindole **2** and 2,3-diphenylindole **3** could have occurred by the abstraction of H<sup>+</sup> from the methyl or benzyl substituent by the calcium oxide catalyst followed by cyclization and rearrangement to give the final product (Scheme 3). It is interesting to note that the presence of methyl and benzyl groups on the nitrogen of 2-aminobenzophenone changed its chemistry and afforded other products, not observed with the unsubstituted aromatic amine, during thermal decomposition. Hence, a variety of other products may be obtained from thermal decomposition reactions by introducing other substituents on the aromatic amine substrates.

## EXPERIMENTAL

Melting points are uncorrected. Column chromatography was performed on silica gel (Wakogel C-200). Unless otherwise stated, anhydrous sodium sulfate was employed as the drying agent. The IR spectra were determined on a Hitachi model 270-30 IR Spectrophotometer. The <sup>1</sup>H and <sup>13</sup>C NMR spectra were determined at 500MHz and 125MHz, respectively, on a Varian Unity plus-500W NMR Spectrophotometer, using tetramethylsilane as the internal standard.

### General Procedure for the Thermolysis Reaction<sup>10</sup> of *N*-Alkylated-2-aminobenzophenones.

Elemental analysis apparatus (Micro Elemental Analyzer, Mitamura Riken Kogyo Inc.) was used for the thermolysis reaction. Granules of calcium oxide were obtained by grinding large pieces of calcium oxide (Nakalai Tesque, Inc.) and collecting particles which passed through the 5 mm sieve and retained by the 2 mm sieve. A quartz tube (66 cm in length, 12 mm i.d.) was packed to a length of 28 cm with the calcium oxide granules (18.0 g). The tube was positioned in the horizontal stationary furnace with heating coils (38 cm in length). The tube was then purged with N<sub>2</sub> gas at a rate of about 19 mL/min and kept at this condition throughout the experiment. The stationary furnace was heated to the desired reaction temperature (400-560 °C). Starting material (1.0 mmole) was weighed into a quartz boat and placed inside the reaction tube at 3 cm from the stationary furnace and vaporized by the traveling furnace under N<sub>2</sub> gas environment. When the desired reaction temperature was 400 °C, 450 °C or 500 °C, the stationary furnace was heated to 400 °C, 450 °C or 500 °C while the traveling furnace was heated to 560 °C. When the desired reaction temperature was 560 °C, the stationary furnace was heated to the desired temperature while the traveling furnace was heated 50 °C higher than the reaction temperature. The traveling furnace was set to motion gradually, reached the stationary furnace in 35 minutes and kept for 5 minutes at this state. Products which came out from the outlet (5 mm i.d.) of the quartz tube were collected in a vessel cooled with ice-water. The products were extracted with acetone. After removal of

the acetone, the residue was chromatographed on a silica gel column and eluted with benzene, benzene-hexane or hexane-EtOAc to give various products. Structures of the products were determined from their spectra. 2-Phenylindole **2**, acridine **4**, and phenanthridine **5** were identified by comparison of the IR,  $^1\text{H}$  NMR and  $^{13}\text{C}$  NMR spectra with those of commercially available samples while 2,3-diphenylindole **3** was identified by comparison of its spectral data with literature value.

### Synthesis of 2-methylaminobenzophenone **1a** and 2-dimethylaminobenzophenone **1b**.

2-Aminobenzophenone (1.978 g, 10.03 mmol) was placed in a 50 mL round bottom flask and added with dimethyl sulfoxide (4mL), tripotassium phosphate (1.589 g, 7.49 mmol), and methyl iodide (1.0 mL, 16.06 mmol). The mixture was heated in an oil bath at 50 °C for 2 h. The progress of the reaction was monitored by thin layer chromatography. After 2 h, methyl iodide (0.8 mL, 12.85 mmol) was again added and the mixture heated for another 1 h in the oil bath at 50 °C. The mixture was then extracted with EtOAc, washed with water and the organic layer separated and dried over anhydrous sodium sulfate. The filtrate was concentrated in a rotary evaporator. The resulting solution was chromatographed on a silica gel column using hexane:EtOAc (15:1) as eluting solvent. The reaction yielded 2-methylaminobenzophenone **1a** (0.769 g, 36%), yellow crystals recrystallized in EtOH, and 2-dimethylaminobenzophenone **1b** (0.790 g, 35%), yellow liquid.

**2-Methylaminobenzophenone (1a).**<sup>11</sup> mp (EtOH) 66-67 °C (lit.,<sup>11</sup> mp 65-69 °C); IR (KBr) 3340  $\text{cm}^{-1}$  (NH), 1616  $\text{cm}^{-1}$  (CO);  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ):  $\delta$  2.97 (d,  $J=5.0$  Hz, 3H,  $\text{CH}_3$ ), 6.54 (dd,  $J=8.0$  Hz and 8.0 Hz, 1H, Ar-H), 6.76 (d,  $J=8.5$  Hz, 1H, Ar-H), 7.40-7.52 (m, 5H, 5 Ar-H), 7.59 (d,  $J=8.0$  Hz, 2H, 2 Ar-H), 8.54 (broad s, 1H, N-H);  $^{13}\text{C}$  NMR: ( $\text{CDCl}_3$ ):  $\delta$  29.4 (q), 111.1 (d), 113.6 (d), 117.2 (s), 128.0 (d), 128.9 (d), 130.6 (d), 135.0 (d), 135.5 (d), 140.6 (s), 152.7 (s), 199.3 (s).

### Synthesis of 2-benzylaminobenzophenone **1c** and 2-dibenzylaminobenzophenone **1d**.

2-Aminobenzophenone (1.975 g, 10.01 mmol) was placed in a 50 mL round bottom flask containing dimethyl sulfoxide (4 mL). Tripotassium phosphate (1.601 g, 7.54 mmol) and benzyl bromide (1.5 mL, 12.64 mmol) was then added and the mixture was heated in an oil bath at 50 °C for 3 h. The progress of the reaction was monitored by thin layer chromatography. After 3 h, benzyl bromide was added (1.0 mL, 8.42 mmol) and heating was continued for another 2 h. The resulting solution was extracted with

EtOAc, washed with water and the organic layer was separated. The organic layer was dried with anhydrous sodium sulfate. The filtrate was then concentrated in a rotary evaporator. The resulting solution was chromatographed on a silica gel column using benzene:hexane (3:1) as the eluting solvent. The reaction yielded 2-benzylaminobenzophenone **1c** (1.208 g, 42%), yellow crystals recrystallized in hexane, and 2-dibenzylaminobenzophenone **1d** (1.171 g, 31%), yellow liquid.
